SPATIAL COMPUTING · HARDWARE-FACING TECHNOLOGY

REDACT

REAL-TIME OBJECT INSPECTION AND SPATIAL CONTEXT

01 / TECHNICAL OBJECTIVE

REDACT is a technology concept for augmented-reality hardware that explores how object-focused inspection can operate within a spatial computing environment. The development objective is to connect target selection, contextual information, and inspection-state feedback in a compact, device-appropriate interaction loop.

DOMAIN	AR / SPATIAL UX
FOCUS	OBJECT INSPECTION
INPUTS	PLATFORM-SUPPORTED
STAGE	PROTOTYPE CONCEPT

02 / SYSTEM CONCEPT

03 / DEVELOPMENT COMPONENTS

- **Target acquisition:** define a supported method for selecting or identifying an object.
- **Spatial association:** investigate how inspection information relates to a target in the user's view.
- **State management:** represent idle, targeted, inspecting, and dismissed states.
- **Context delivery:** present relevant information with attention to legibility and visual obstruction.

04 / ENGINEERING PATH

- Prototype the interaction and state model.
- Map required functions to APIs available on the target AR hardware.
- Implement supported input and spatial behaviors in the native development environment.
- Test tracking stability, latency, readability, comfort, and recovery from loss of target.

TECHNICAL SCOPE AND VALIDATION

REDACT is a development concept, not a claim of completed hardware integration. Object recognition, spatial anchoring, gaze or hand input, and persistent tracking depend on the capabilities exposed by the target device and development SDK. Each capability must be implemented and verified on hardware before being described as functional.
